WebRTC

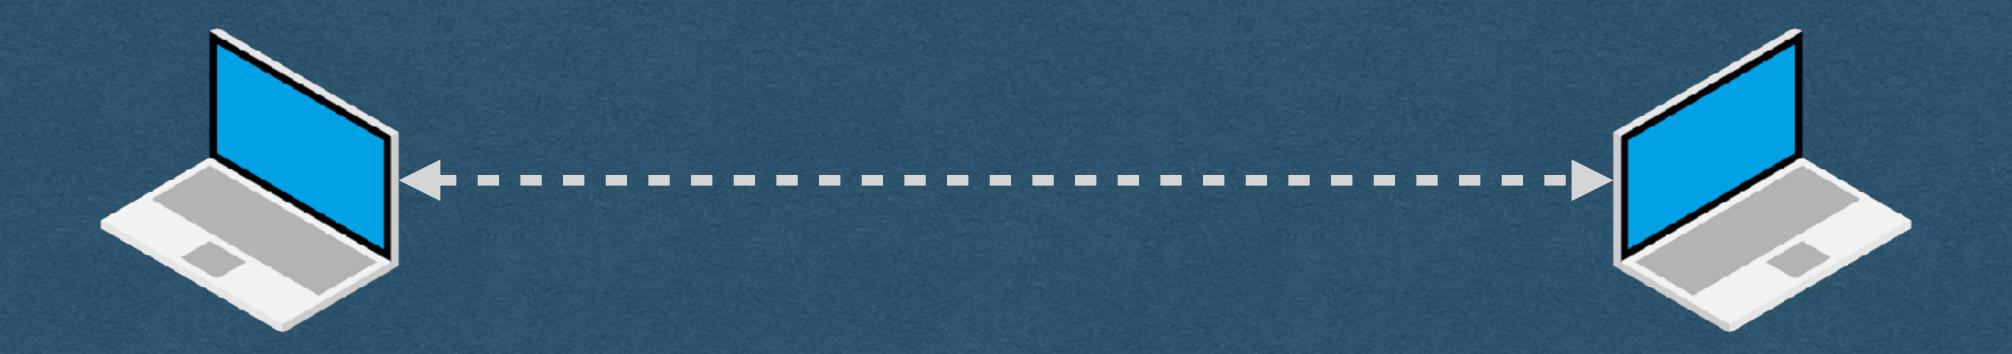

WebRTC

Reminder

- Only need to implement the signaling server for the HW
- Details on what to code in the next lecture

WebRTC

- Need to establish a real-time streaming peer-to-peer connection
- But how?
 - Need the IP address of your peer
 - Need to agree on the details of the connection

- One peer needs to get an offer to the other peer
- This is an offer to establish a connection that contains:
 - audio/visual codec, bitrate, etc details (How to interpret the bytes once the streaming starts)
 - A username fragment ("ice-ufrag") as a unique identifier

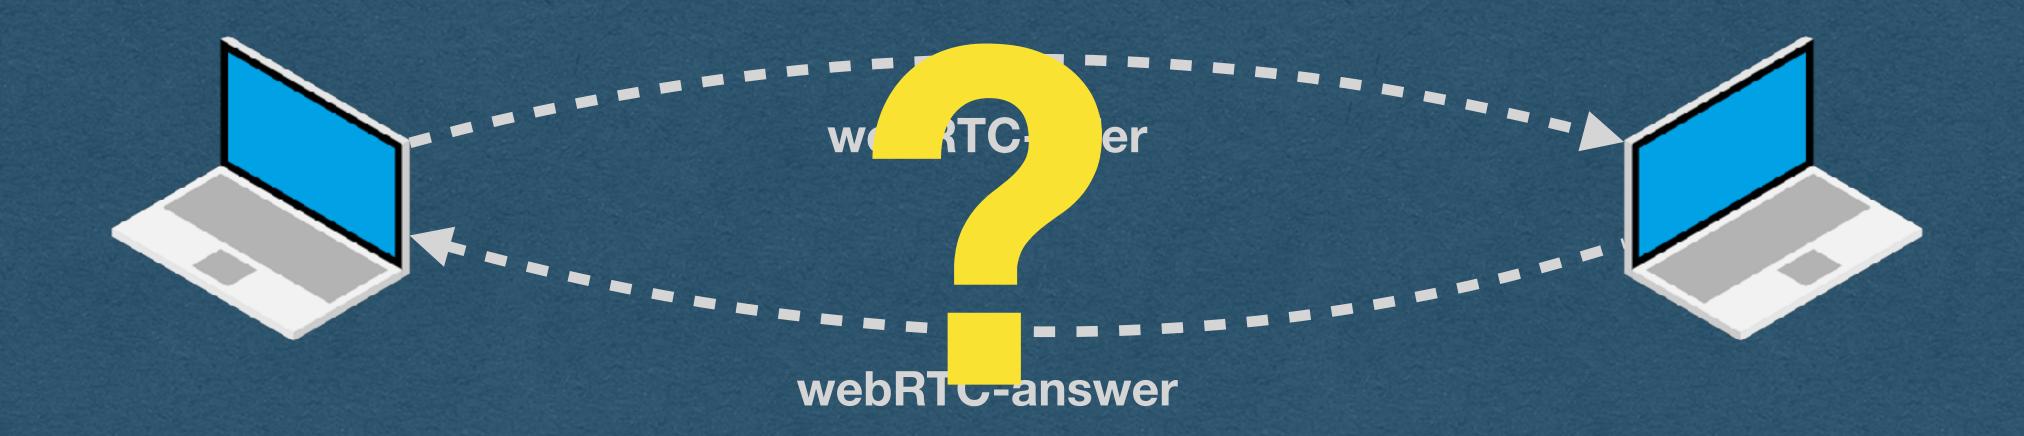

- The peer responds with an answer
- The answer contains their audio/visual data
- Contains their own ufrag so the connection can be identified

Once the answer is received, the peers agree to connect

But there's a problem

How do we send these messages between two peers?

- For usual web traffic with a server:
 - Type in a domain name or click a link containing a domain name
 - Use DNS to lookup the [static] IP address of the server
 - Send a request to the IP address on port 80 or 443

- For peer-to-peer traffic:
 - We need to discover the IP and port of the peer without DNS
 - Peer IP/port can change (dynamic IP)

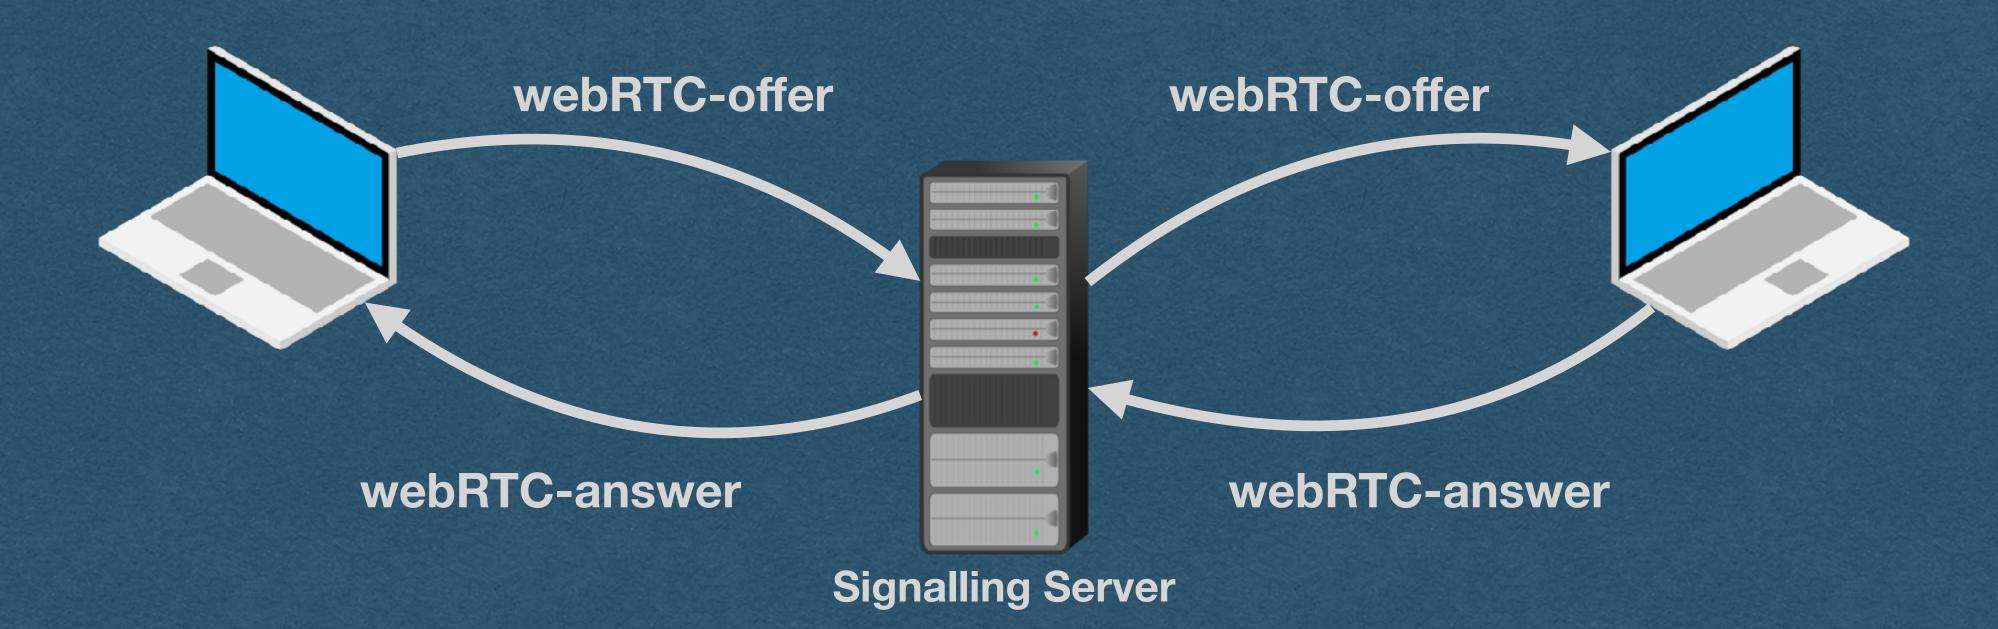

- For peer-to-peer traffic:
 - We need to discover the IP and port of the peer without DNS
 - Peer IP/port can change (dynamic IP)

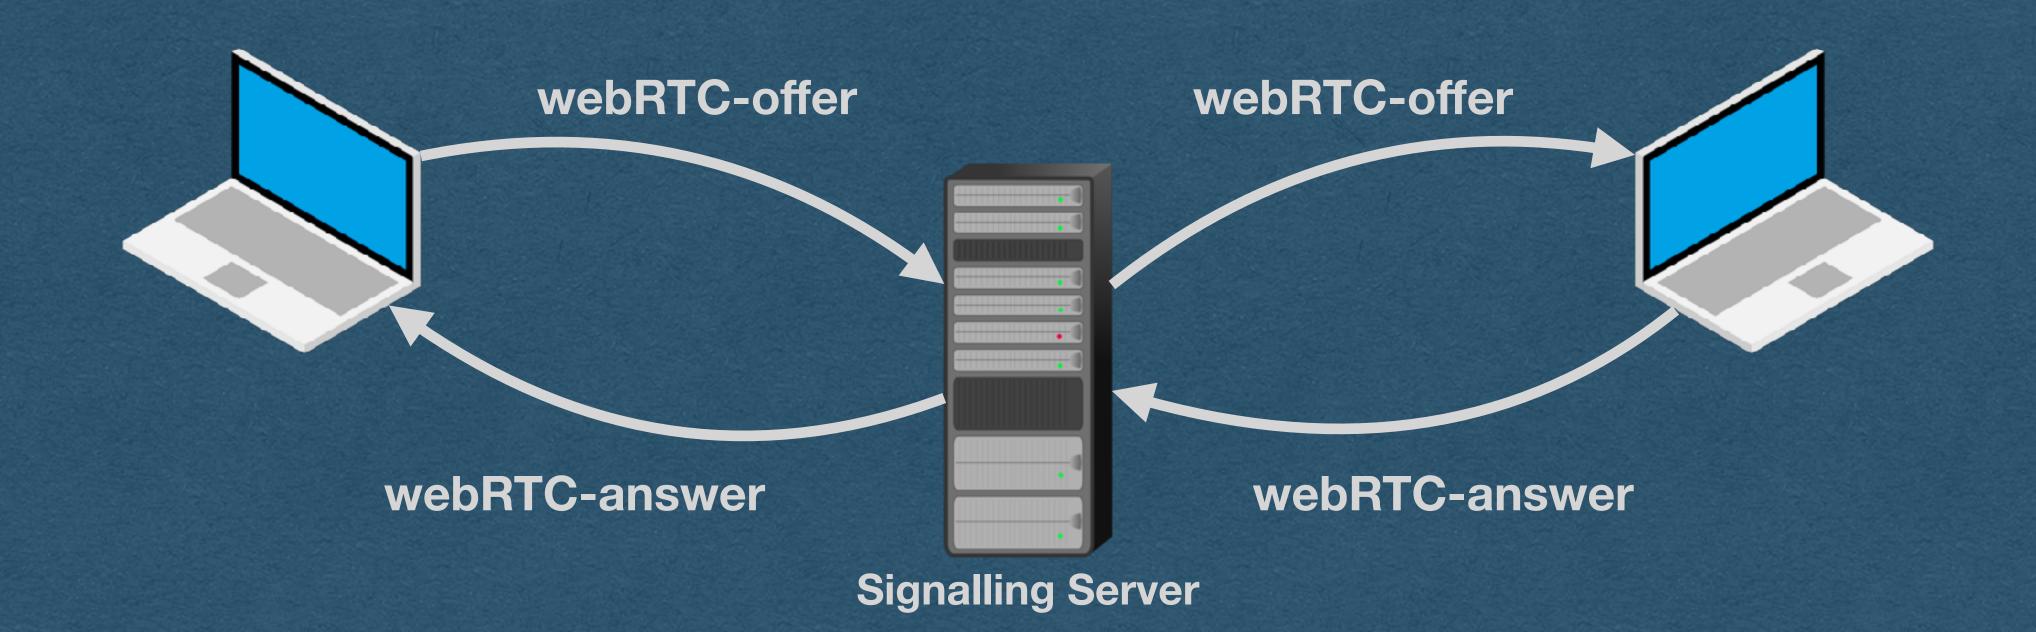

WebRTC - Signalling Server

- Offer and answer are sent through a signaling server
 - On the HW You are the signaling server!!
- Both peers connect to your server
- Send offer/answer to the server and the server forwards the messages to the other peer

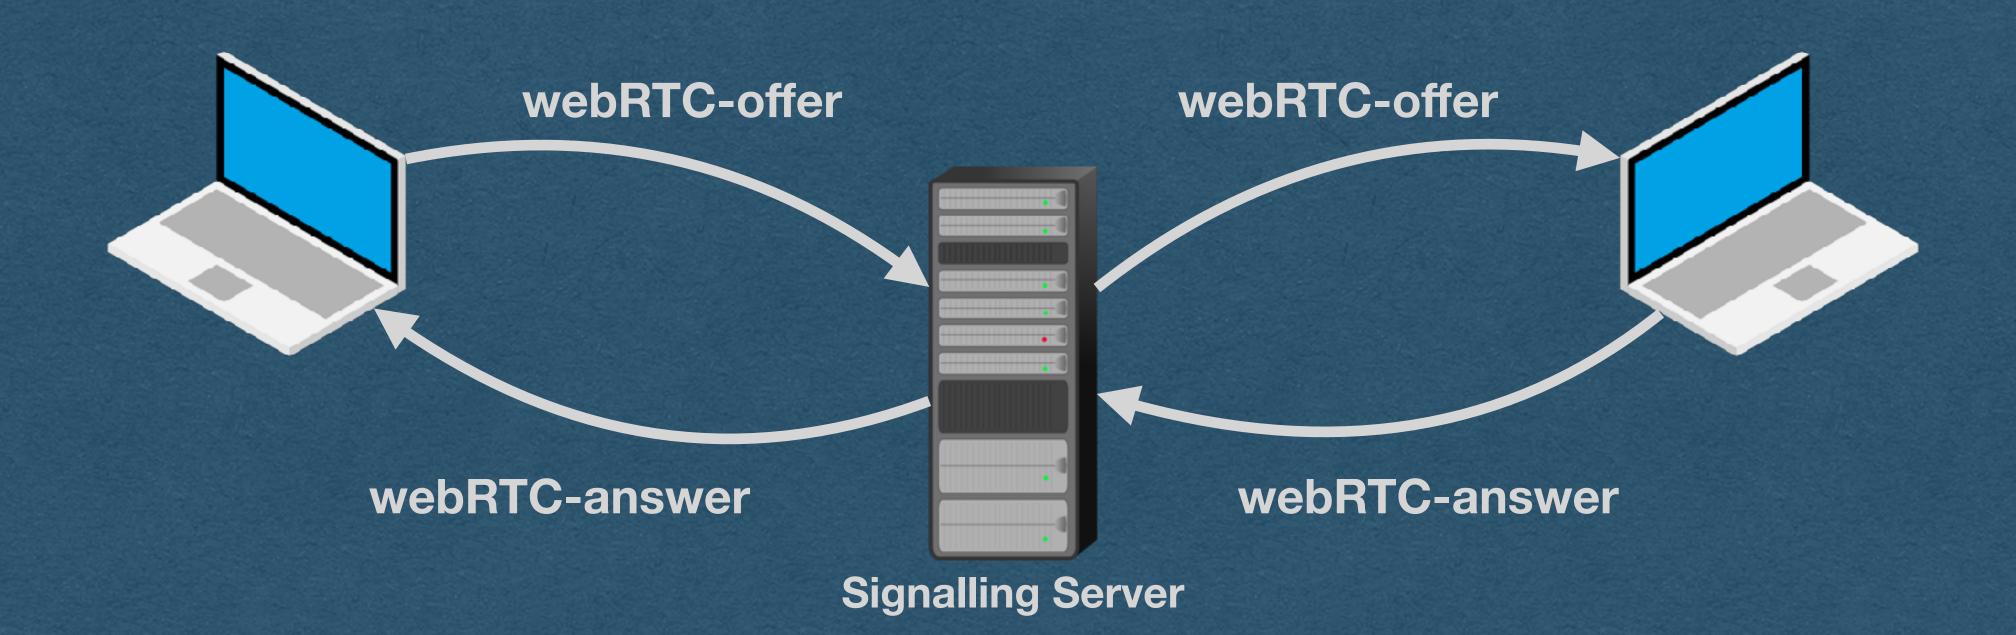

WebRTC - Signalling Server

- We need a method to send these messages
- We'll need a way for the server to be able to send messages to each client in real-time
- Wow! It's really convenient that we have WebSockets!

WebRTC - Signalling Server

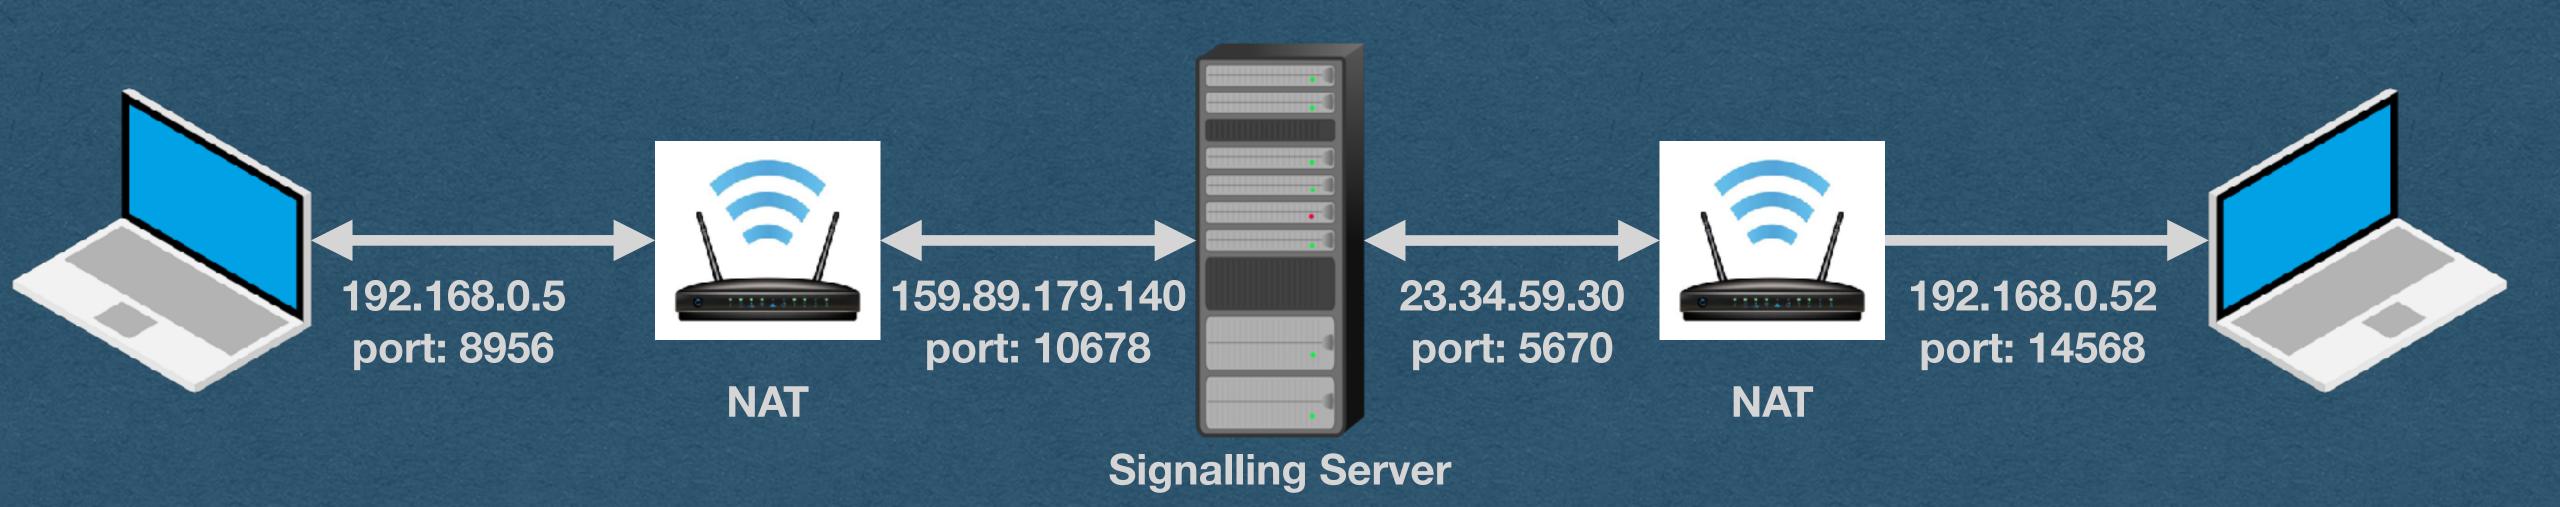

- When your server receives a WebSocket frame containing an offer or answer
 - Send the payload to the other peer over their WebSocket
- We could support any number of peers
 - To avoid the HW from getting too complex, assume there are exactly 2
 WebSocket connections when coding the WebRTC feature

WebRTC - NATs

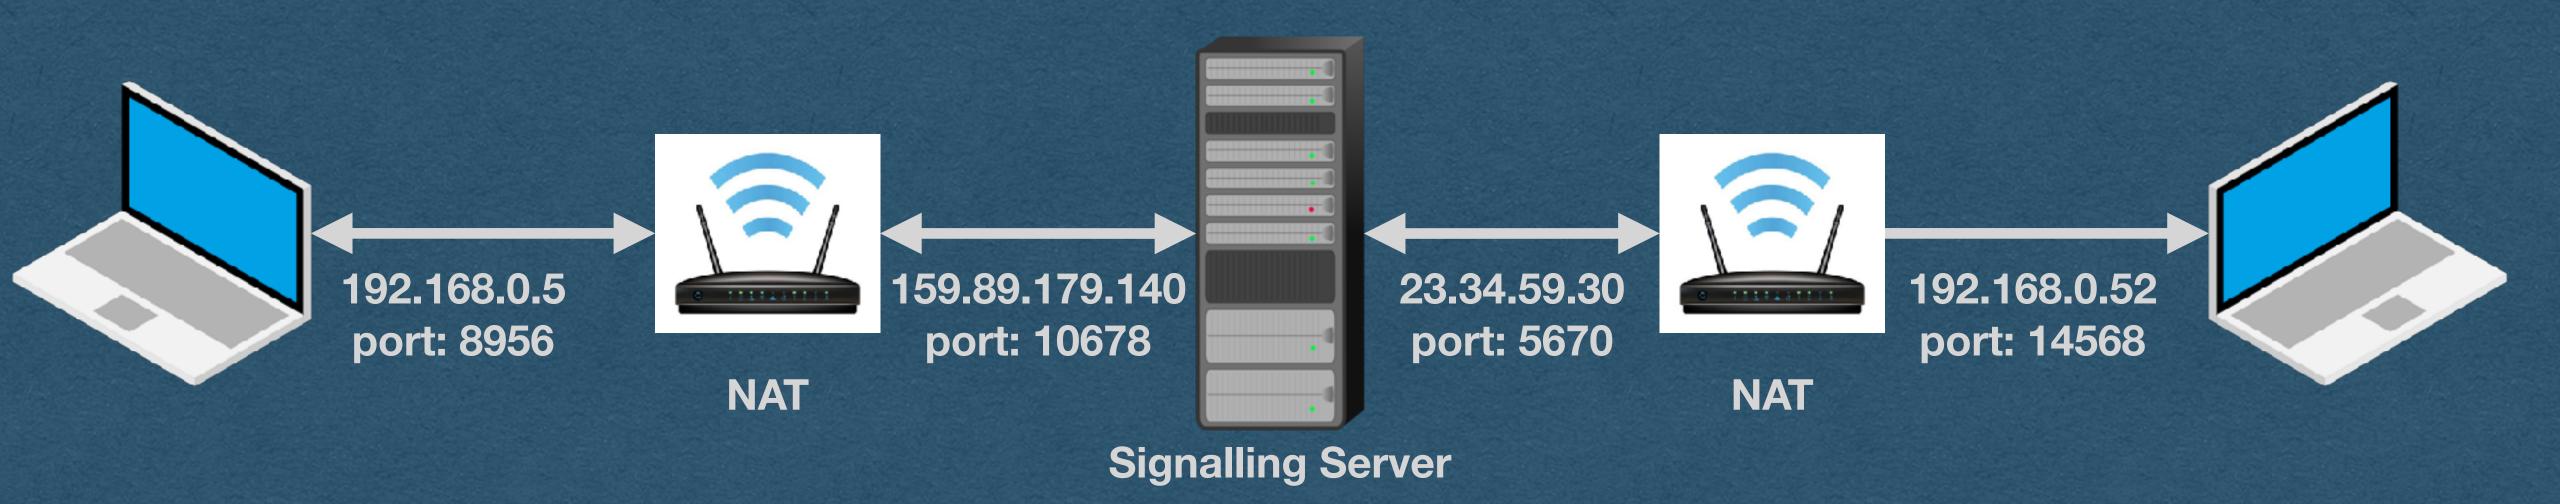

• We have another issue...

How do we know the IP address and port for each peer?

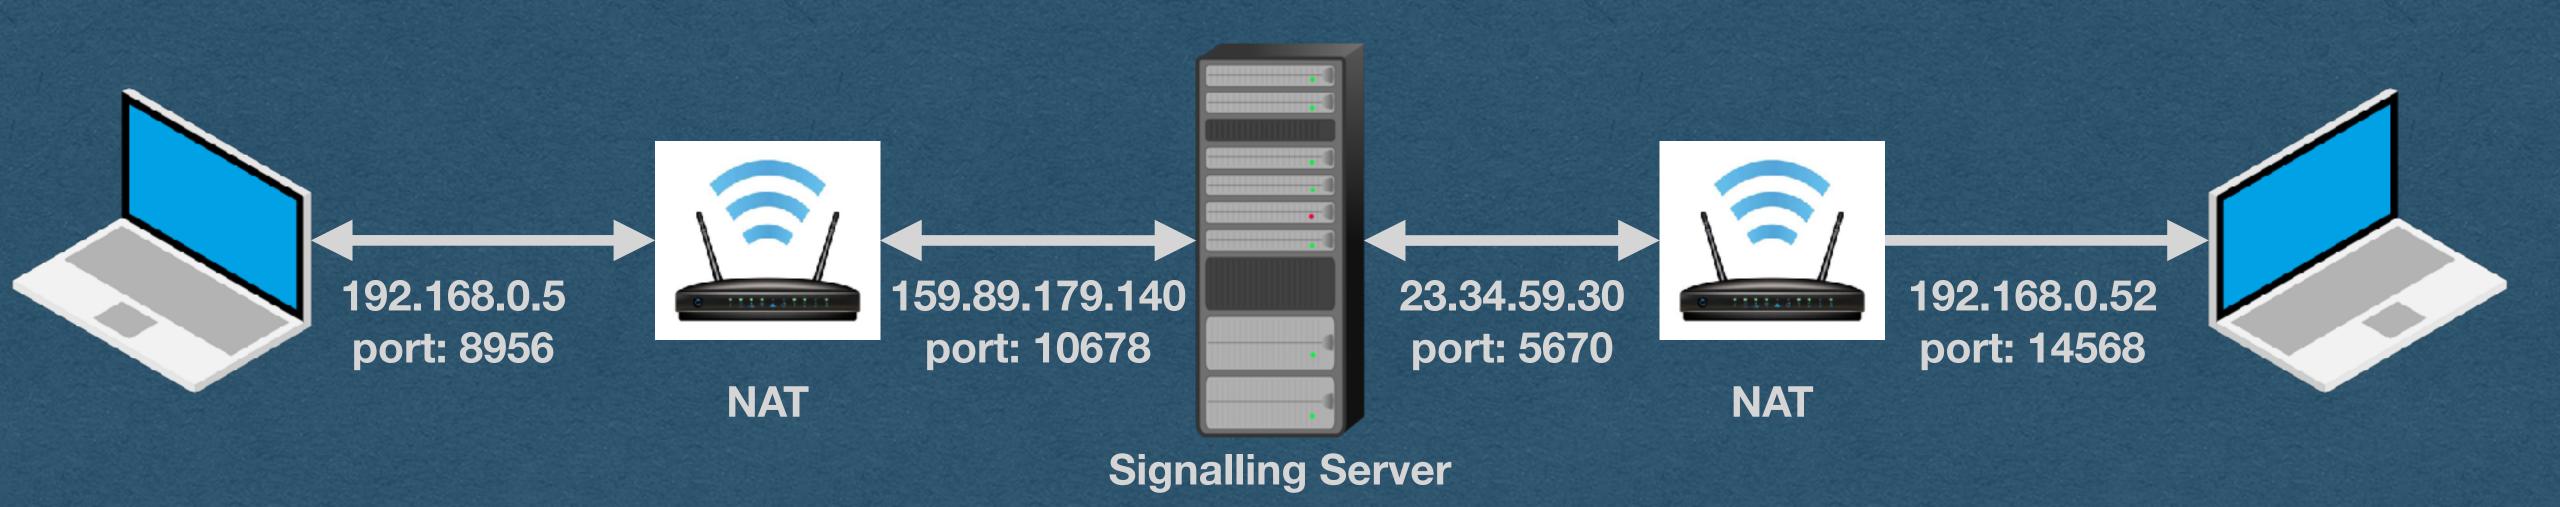

WebRTC - NATS

- Devices are commonly "hidden" behind NAT routers
 - Network Address Translation
- With NAT:
 - you have a local IP address for communication on your local network
 - When communicating outside your network, the NAT router send your message using a public IP address and can change your port number

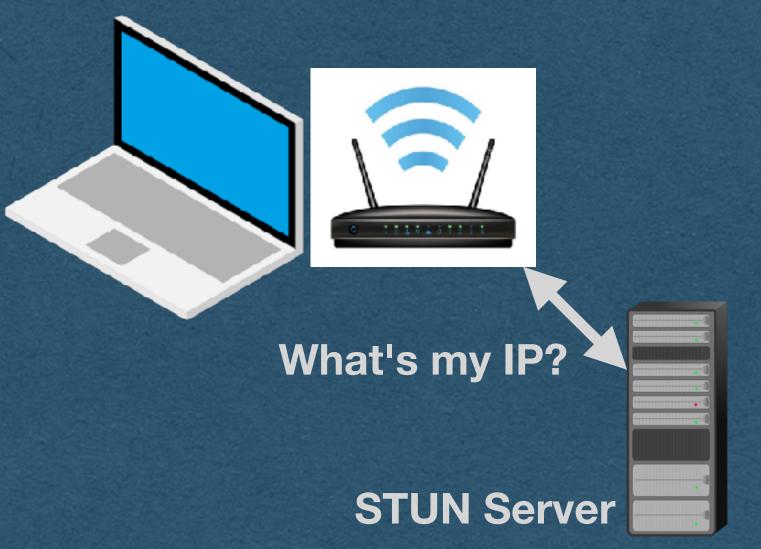

WebRTC - NATS

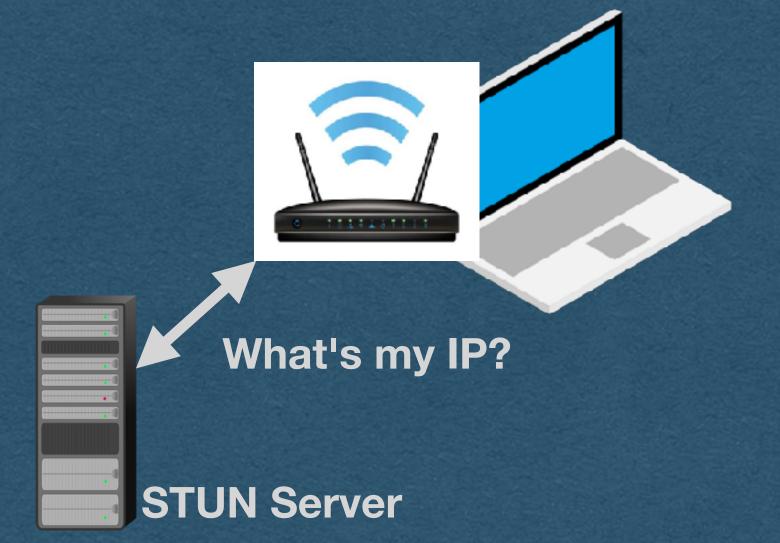

- With NAT:
 - Many devices on a local network can share a single public IP address
 - Each device does not know its public IP/port used when it communicates to the outside world
 - [Also the problem that port-forwarding solves]

WebRTC - STUN Server

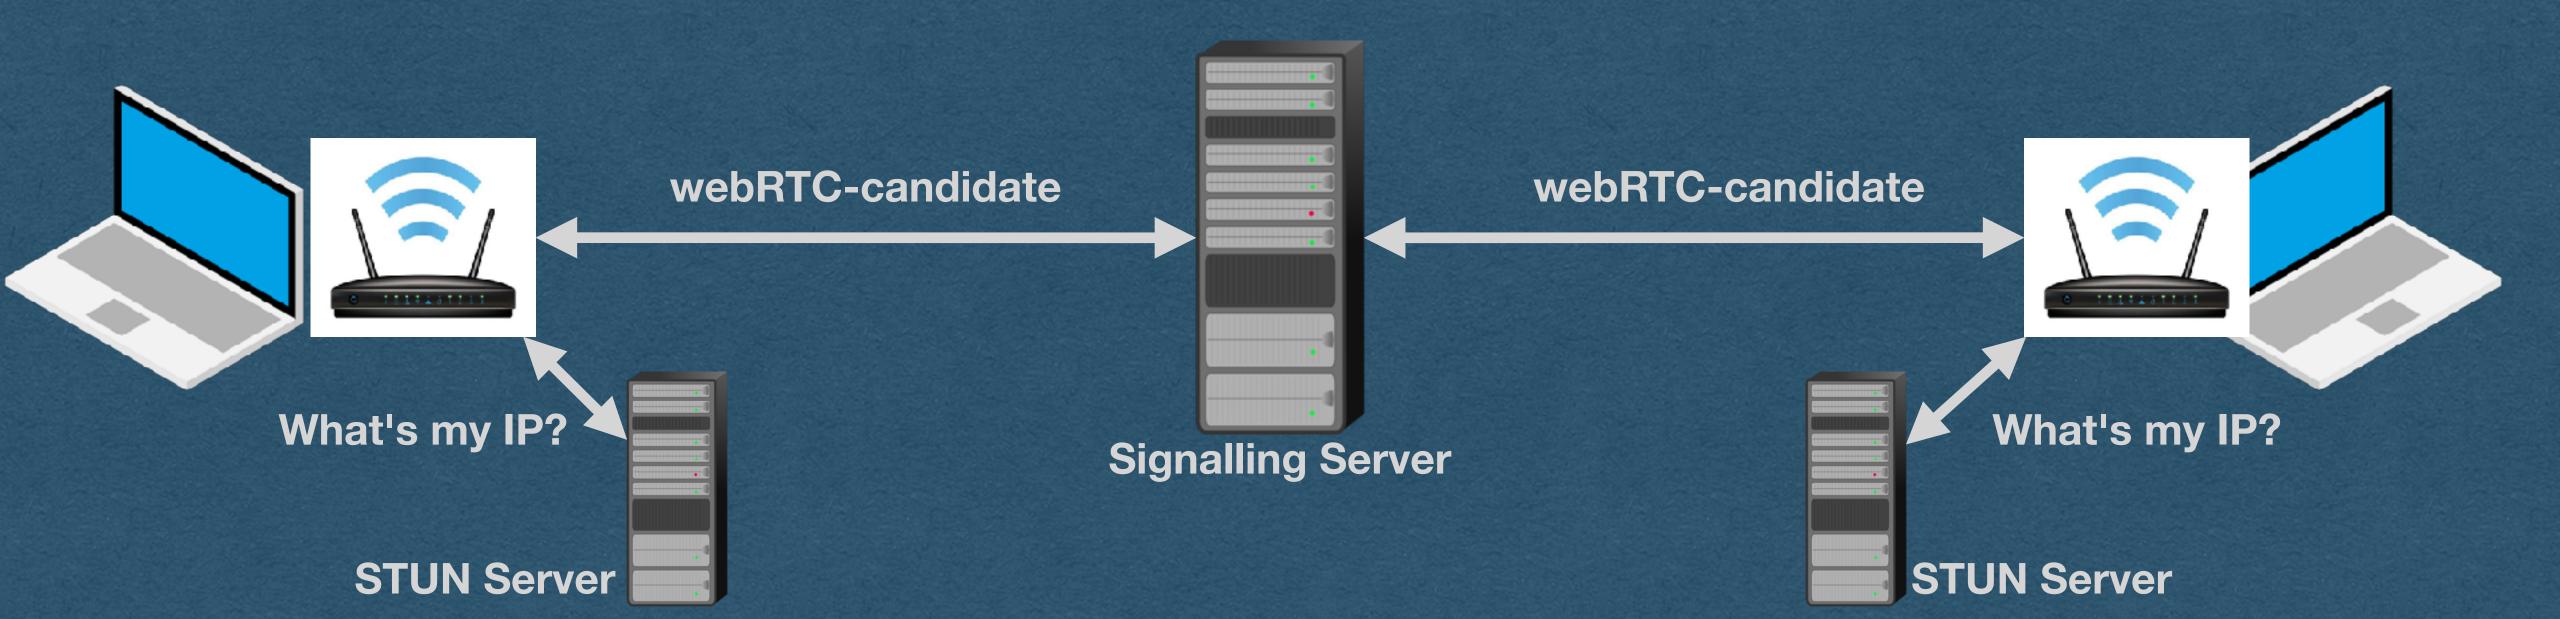

- Solution: Use a STUN (Session Traversal of User Datagram Protocol)
 Server
- Each peer connects to a STUN server and asks for their public IP/port
- STUN server checks the origin IP/port and informs the client
- (We'll use Google free STUN server (stun2.1.google.com:19302)

WebRTC - ICE Candidate

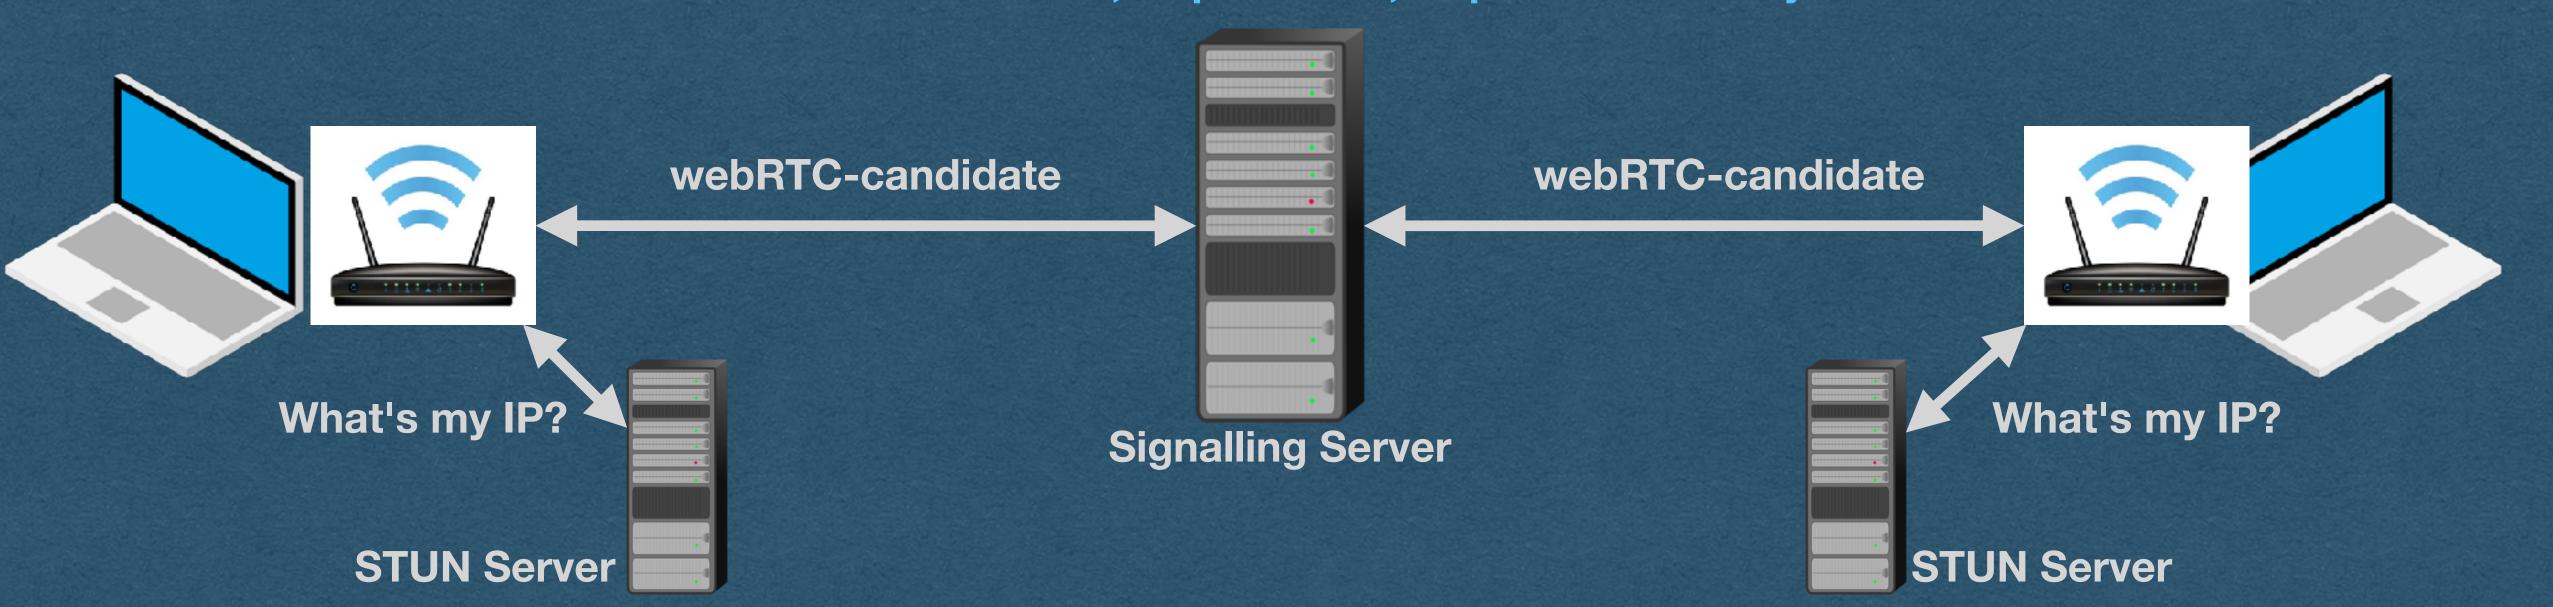

- Each peer sends their public IP/port, and connection information, in an ICE (Interactive Connectivity Establishment) candidate message
- Whenever your signaling server receives an ICE candidate, forward it to the other peer

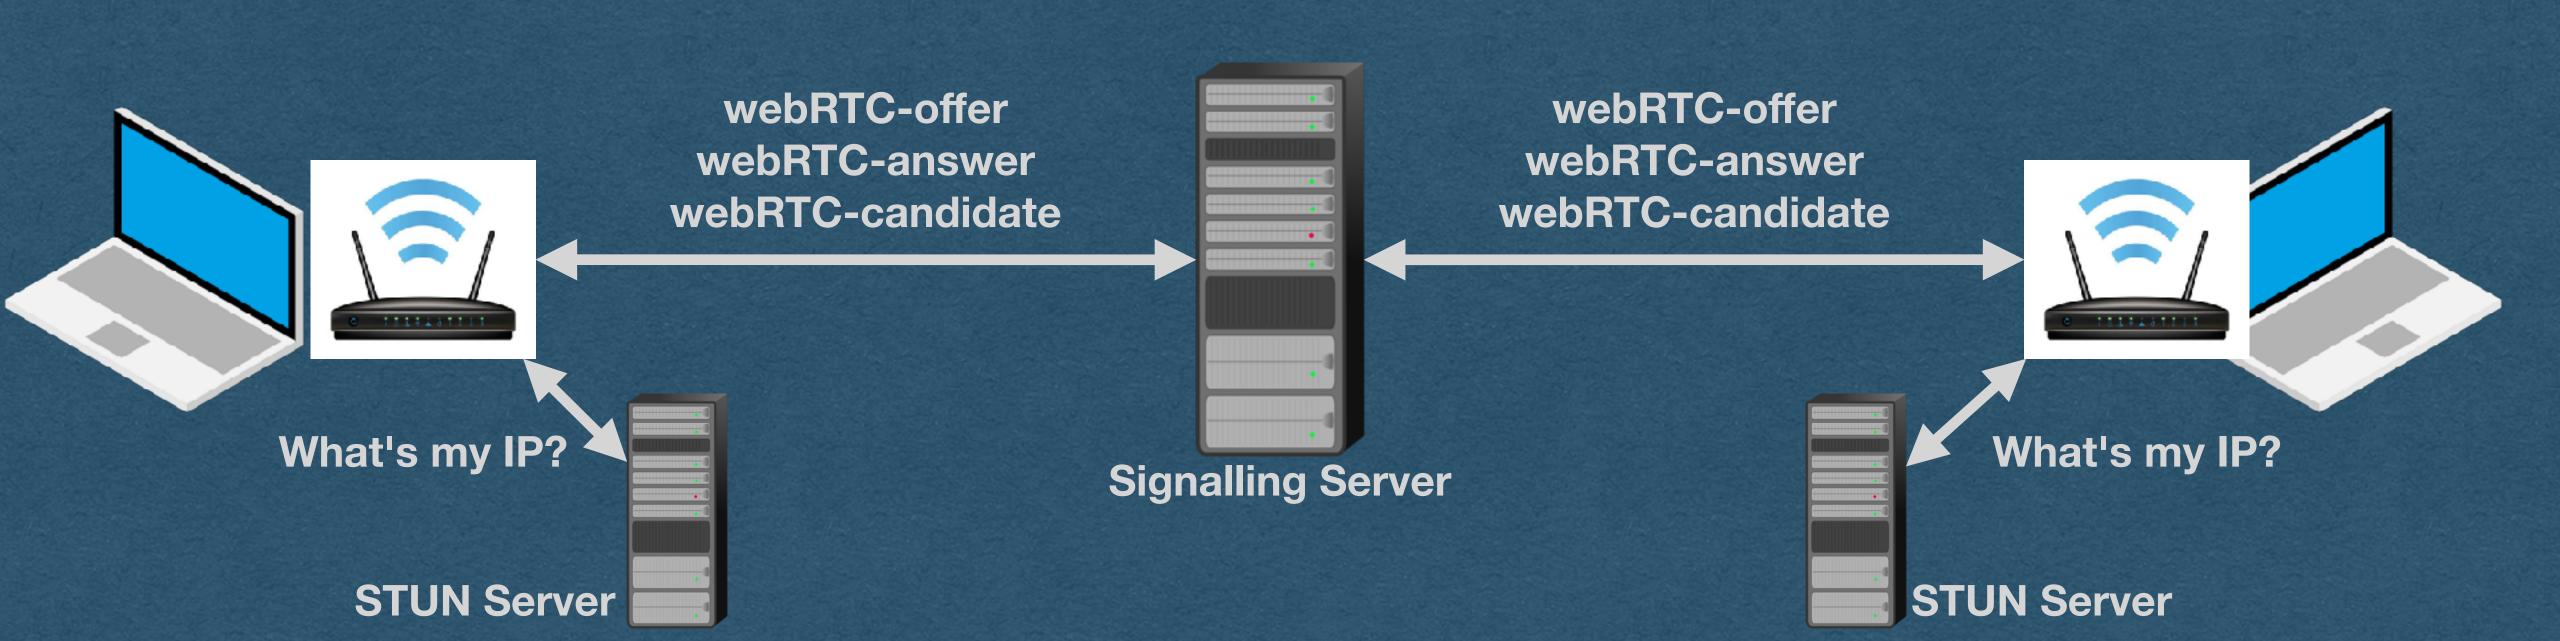

WebRTC - ICE Candidate

- Candidate contains:
 - Connection type UDP, not TCP
 - IP/port Local in this example
 - Username fragment Uniquely identifies the connection

{"candidate":"candidate:2382557538 1 udp 2122260223 192.168.1.19 54090 typ host generation 0 ufrag FGP/ network-id 1 network-cost 10","sdpMid":"0","sdpMLineIndex":0}

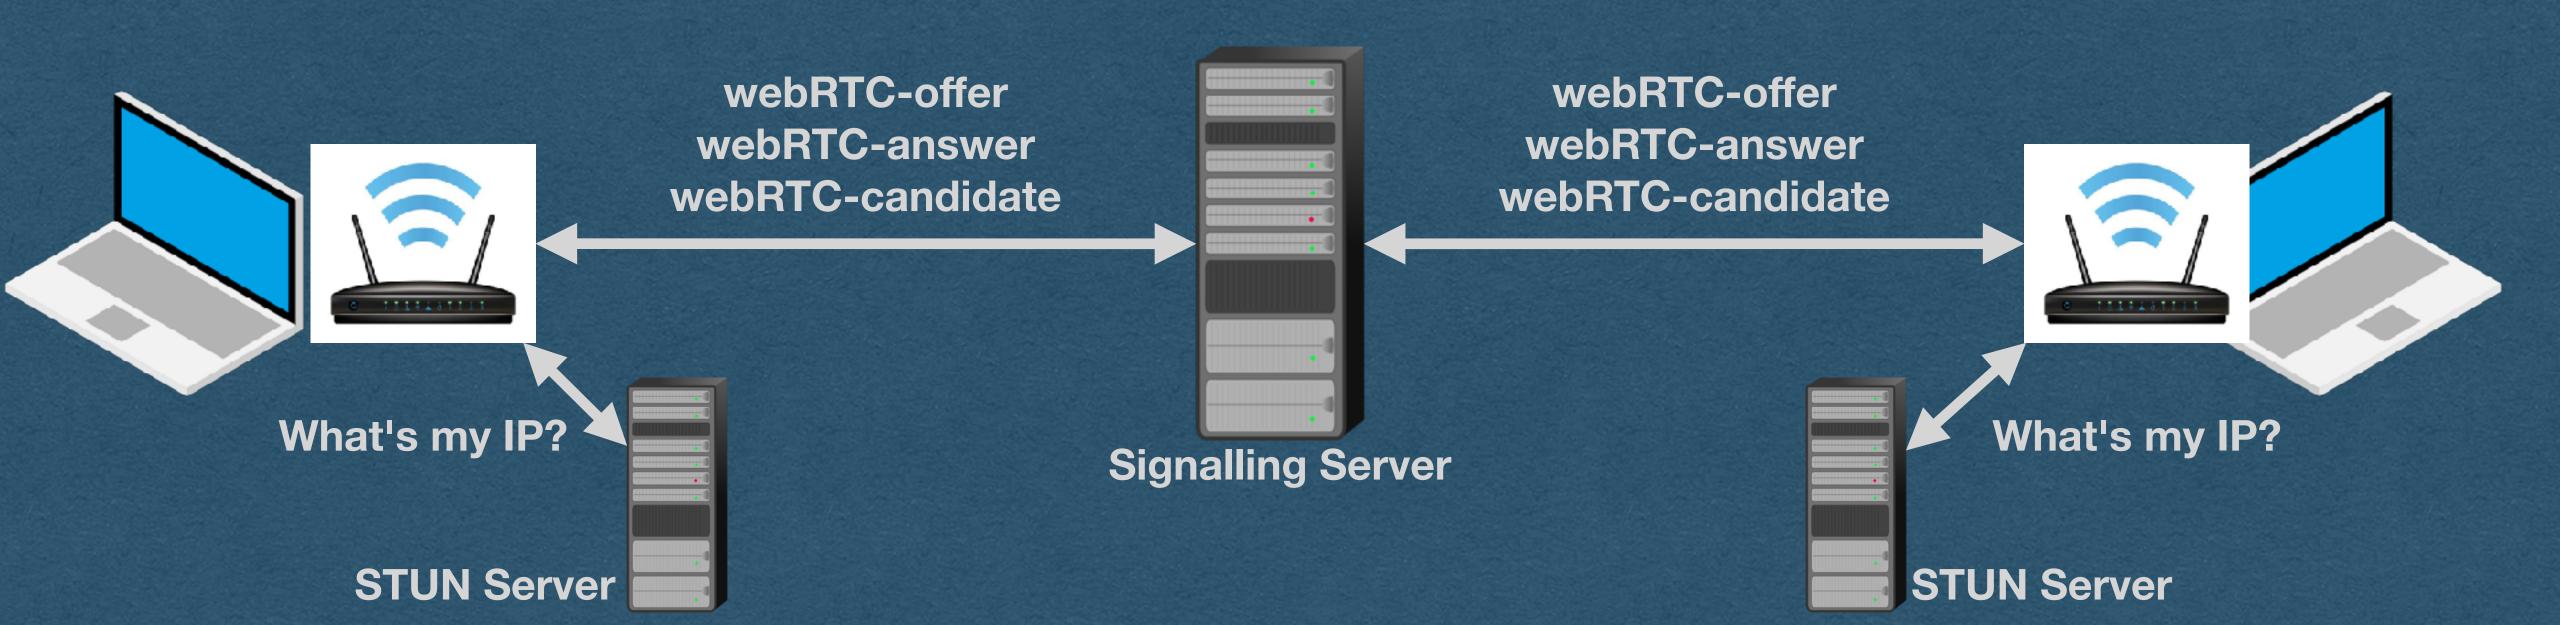

And now we can establish a peer-to-peer connection!

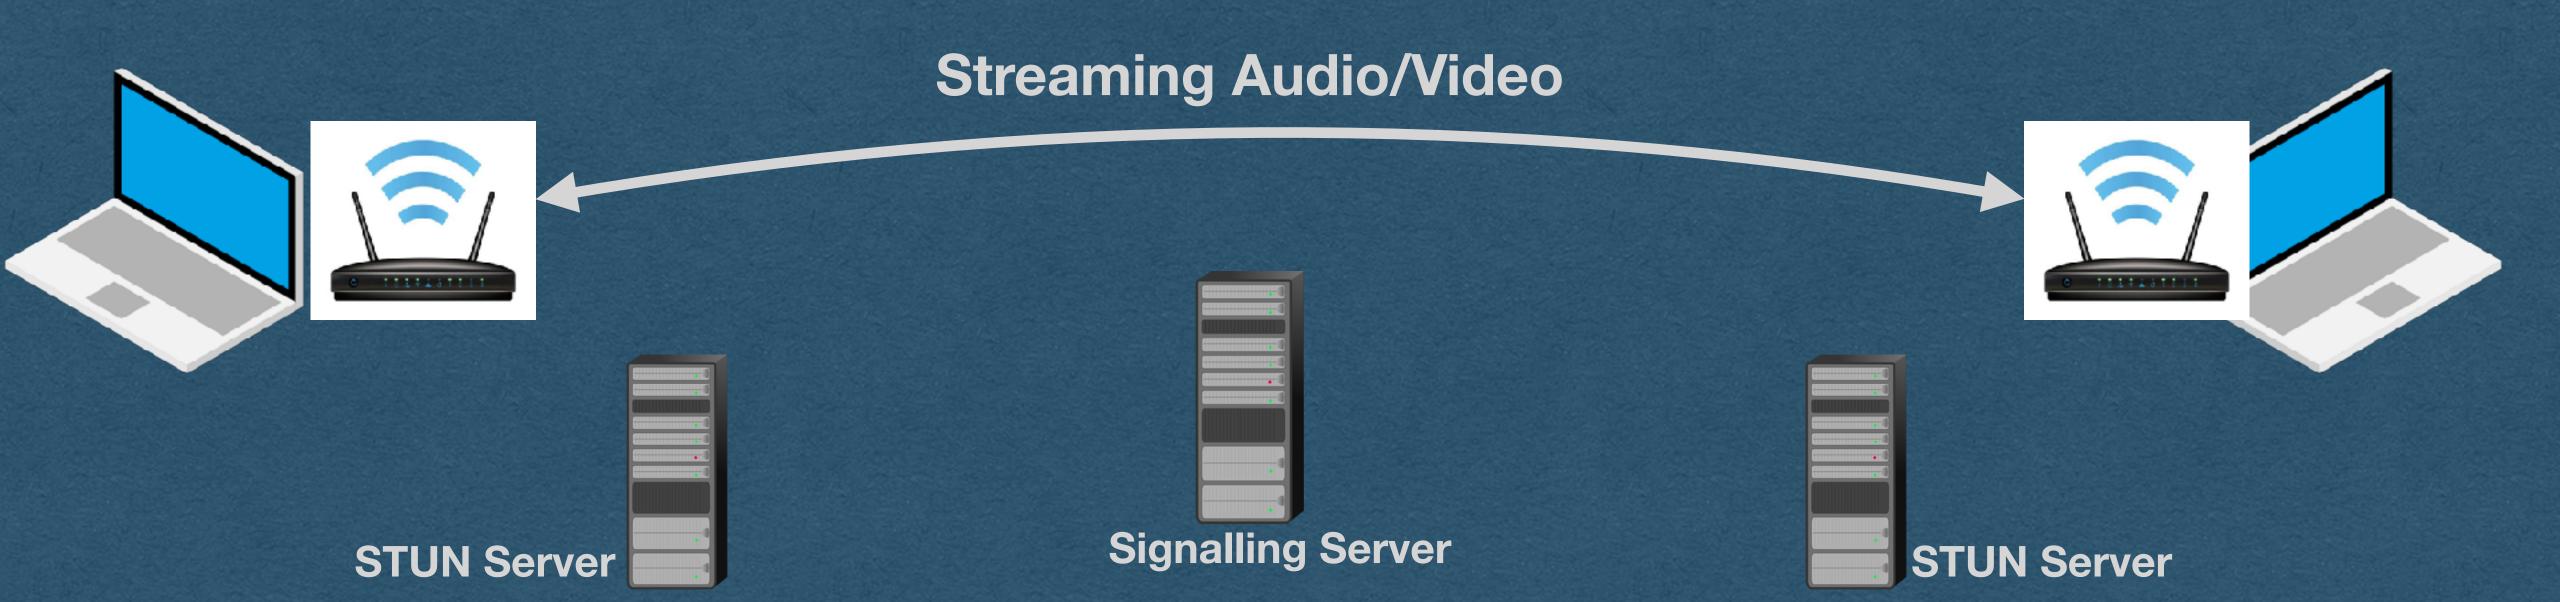

WebRTC - Summary

- One peer sends an offer to the other
- Other peer responds with an answer
- Both peers get their public IP/port from their STUN Servers
- Both peers send their ICE candidates to the other

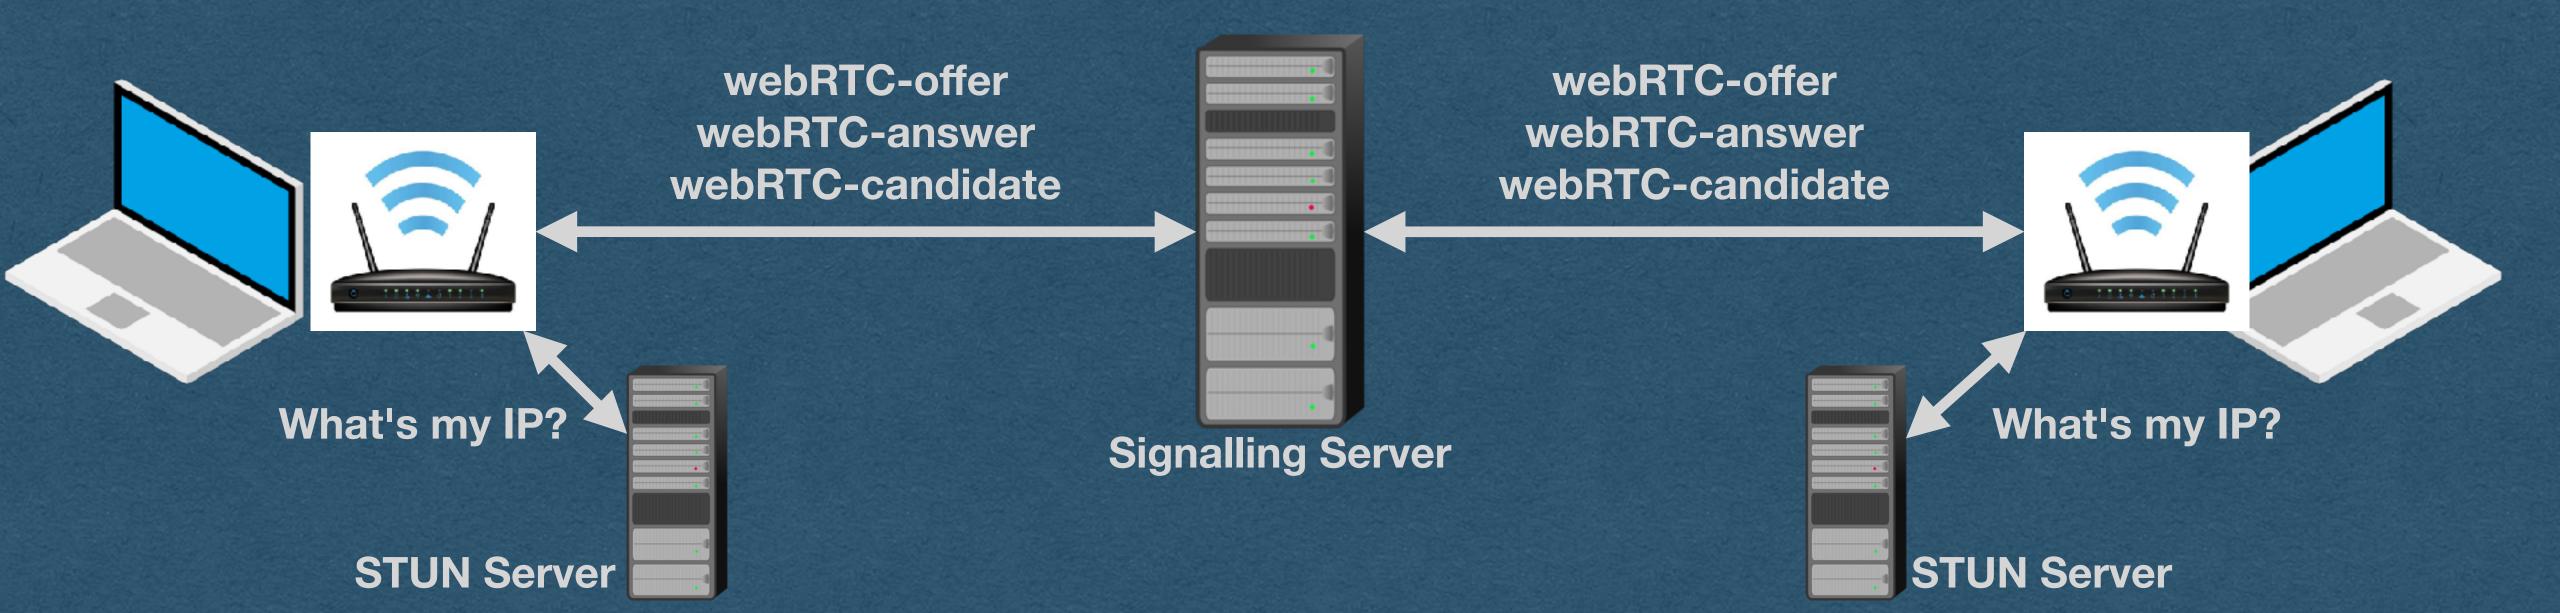

WebRTC - Summary

- Once the connection is established
- The servers step aside and the client stream directly to each other
 - True peer-to-peer!

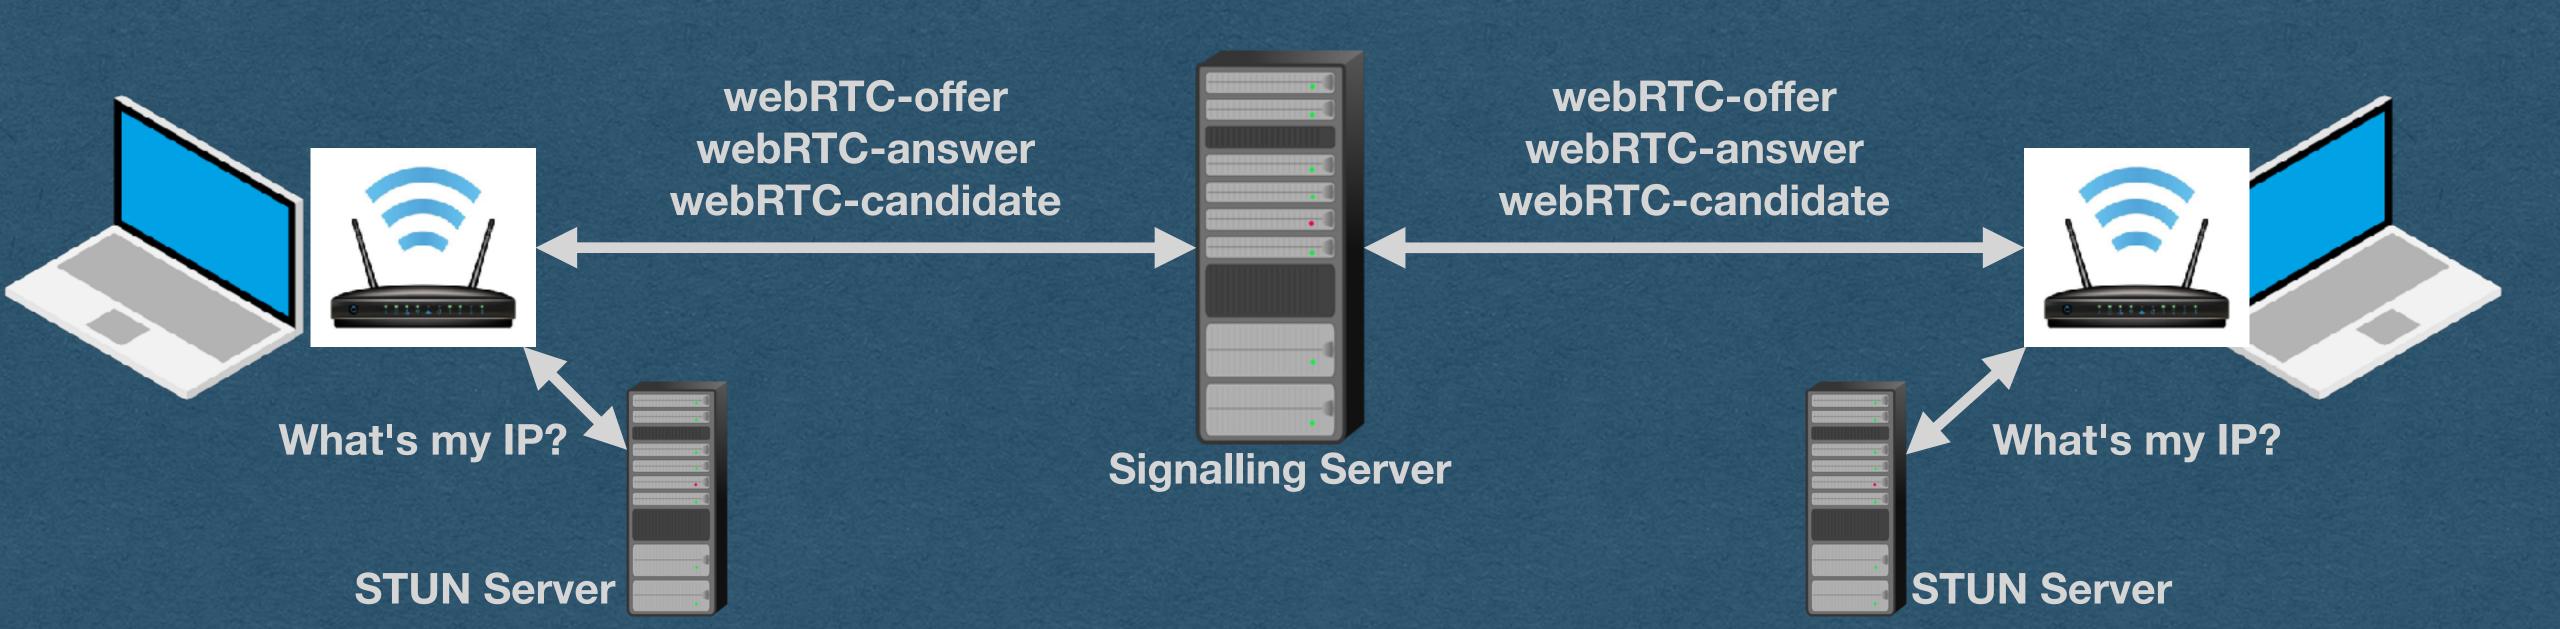

WebRTC - Summary

- Your role in all of this?
 - Forward the offer/answer/candidate messages received from either peer to the other peer
- No need to read/parse/interpret these messages
 - Extract the payload from the WB frame, build a new frame with the exact payload and send it to the other peer

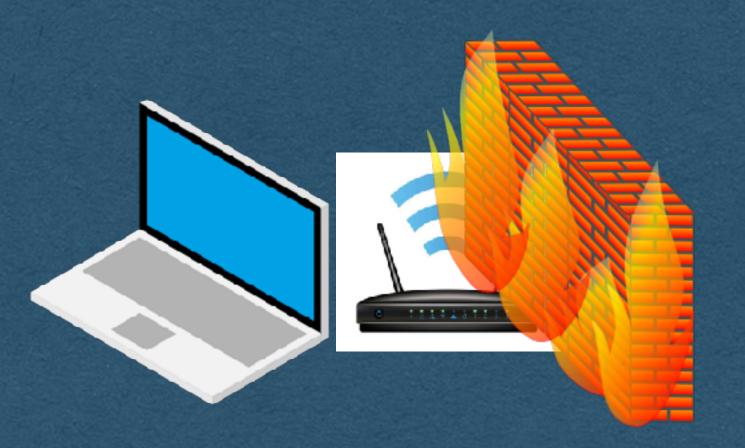

WebRTC - Restrictions

- The browser will not allow WebRTC connections when connected to a site using HTTP (as opposed to HTTPS)
- Must have an excepted connection
 - *Unless connecting over localhost (Let's us test locally)

WebRTC - Restrictions

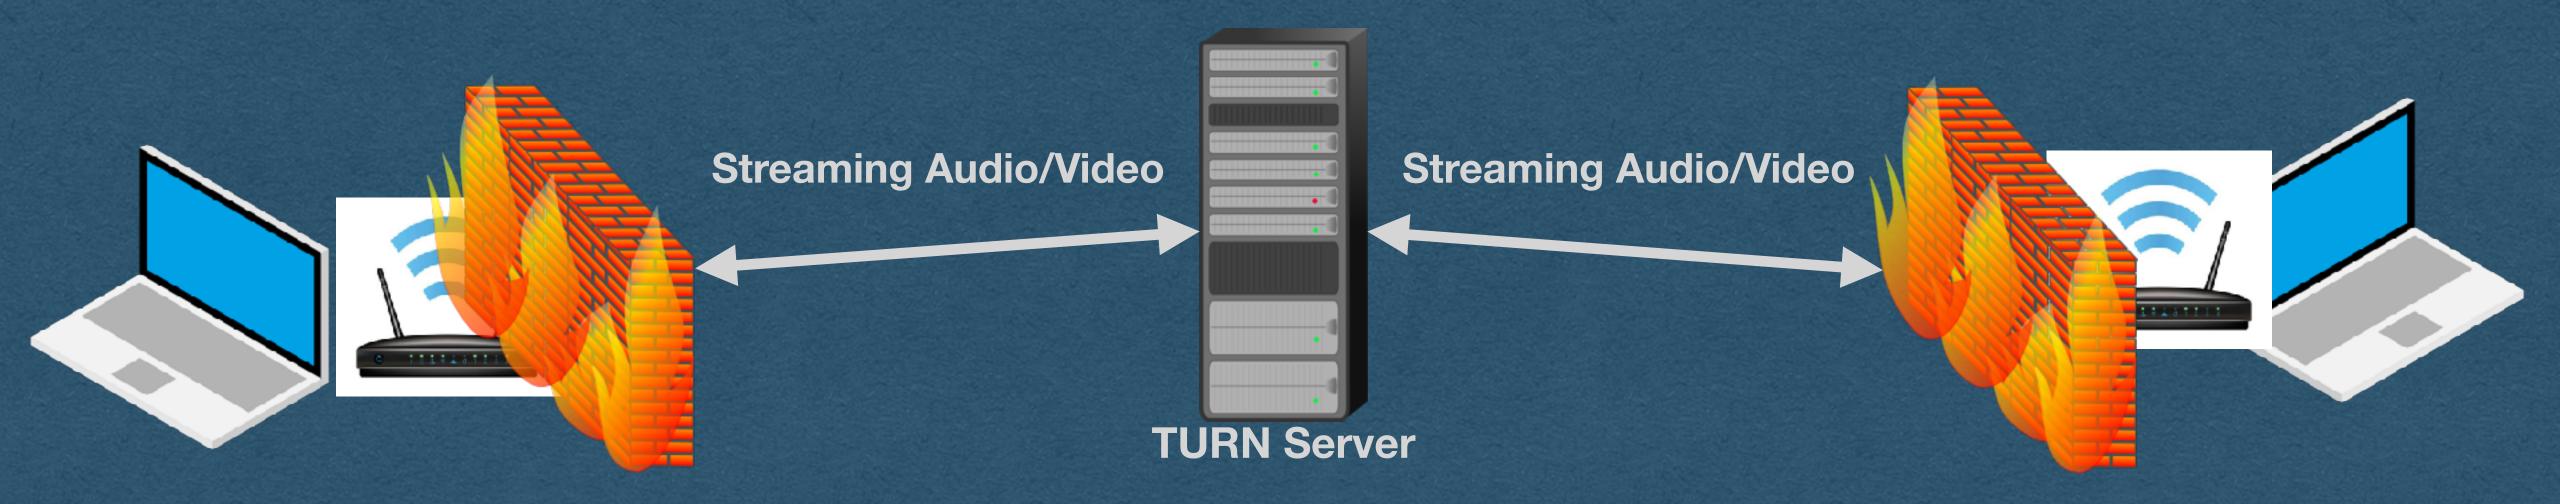

- Sometimes a peer-to-peer connection cannot even be established
 - Can have restrictive firewalls
 - Dynamic NATs might change your port unexpectedly
 - Organizations might block certain traffic on their network

WebRTC - TURN Server

- I cases where peer-to-peer is blocked
- Use a TURN (Traversals Using Relays around NAT) Server
- After the connection is established using a signaling server, each peer routes their streaming data through a TURN server

WebRTC - TURN Server

 If you ask me... using a TURN server defeats the purpose of using a peer-to-peer technology

• ... Unless you run your own TURN server!
