Encryption

The Problem

- Using HTTP, anyone with access to your packets can see everything you are doing online
 - This includes your passwords!
- Who has access to my packets?
 - Your ISP at home
 - UBIT on campus
 - Tier 1 Networks

• .. and everyone within wifi range of your device!

The Solution

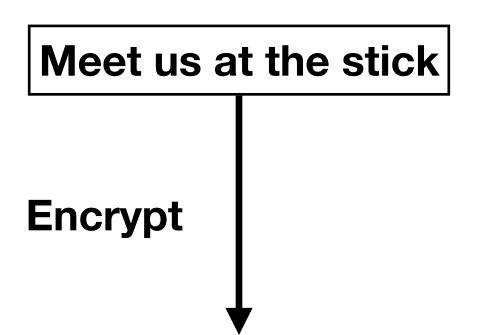

- We'll just add an S to our protocol and call it HTTPS
 - HTTP over TLS

- Overview
 - Background in public key encryption (Today)
 - Symmetric key encryption, key exchange, certificates, CAs (Wednesday)
 - Examples (Friday)

Encryption

- Hide communication from attackers/eavesdroppers
- Want to send a plaintext message
 - Could be HTML, JSON, JavaScript, text, an image, etc
 - Plaintext is a cryptographic term to mean unencrypted
 - We encrypt at the byte level
- Encrypting the plaintext outputs a random looking cyphertext
- No one should be able to read this cypher text except the intended recipient
- Only the intended recipient can decrypt the cyphertext and read the plaintext message

Encryption

Decrypt

Meet us at the stick

Public Key Encryption

- How do we ensure that only the intended recipient can decrypt the message?
 - Public Key Encryption
- Generate a public and private encryption key
 - Private key is kept private
 - Public key is shared with anyone/everyone
- A message encrypted with the public key can only be decrypted by the corresponding private key
- If I want to send a message to someone, I can encrypt the message with their public key

Public Key Encryption

- The public and private key are inherently related
- An attacker must not be able to determine the private key given the public key [In any reasonable amount of time]
- An attacker must not be able to decrypt cyphertext without the private key [In any reasonable amount of time]
- Any public key encryption algorithm must have these property [And more]
 - Math and theory will help us

- RSA Rivest-Shamir-Adleman
 - A public key crypto system with the desired properties [we hope]
- Provides algorithms to:
 - Generate a public/private key pair
 - Encrypt with the public key
 - Decrypt with the private key

Key Generation

- Choose two [large] prime numbers p and q
- $n = p^*q$
- $\lambda(n) = lcm(p-1, q-1)$
- Choose $e < \lambda(n)$ and $gcd(e, \lambda(n)) = 1$
- $d = e^{-1} \mod \lambda(n)$
- Share e and n as the public key
- Keep d as the private key
- Discard p, q, and λ(n)

Encryption

- To send a message m
- Compute c = m^e mod(n)
- Send c

Decryption

- Receive c
- Compute m = c^d mod(n)
- Read m

- RSA key generation gives us: m = m^(e*d) mod(n)
- This means that we can also encrypt with the private key and decrypt with the public key
 - We call this a signature
 - Everyone can decrypt the message so there is no privacy
 - However, there is a guarantee that the author is legitimate (You know I'm the one who sent this message)
 - Useful to sign authentication tokens so the server know that it authorized this user

- What about a brute force attack?
 - Attacker has the public key
 - Keep encrypting "guesses" of the plaintext until the cryptotext matches
- Solution: Use a padding algorithm
 - Add random bits to the end of each message
 - Attacker must guess these random bits
 - Adds security!
 - Unlike salting, this padding can be kept secret and adds entropy
 - We'll discuss salting when we hash user passwords
 - Makes encryption of even short messages secure

Key Generation

- Choose two [large] prime numbers p and q
- $n = p^*q$
- $\lambda(n) = lcm(p-1, q-1)$
- Choose $e < \lambda(n)$ and $gcd(e, \lambda(n)) = 1$
- $d = e^{-1} \mod \lambda(n)$
- Given p, q, and e an attacker can easily compute d (private key)
- Everyone already has e and n (the public key)
- So just factor n to get p and q, then compute the private key

Factoring is hard [We hope]

- There is no publicly know algorithm that can efficiently factor a number
- Worst case is factoring the multiplication of two large primes
 - Exactly what RSA relies on for security
- It has not been proven that factoring is a "hard" problem
 - Quantum computers can factor efficiently
- We call the factoring problem a cryptographic primitive

Encryption

- To send a message m
- Compute c = m^e mod(n)
- Send c

- Everyone knows e and n (The public key)
- An attacker can read c if they are within wifi range
- Just have to compute the discrete log_e of c mod n

Computing a Discrete Log is hard [We hope]

- There is no publicly know algorithm that can efficiently compute discrete logarithms
- This problem is another cryptographic primitive

Public Key Encryption

Java Demo

HTTPS

Man-in-the-middle attack

- The first step in an HTTPS connection:
 - Client requests the server's public key
- An attacker controlling a router in one of the networks handling your packets can intercept this request and replace it with their own public key
- Attacker then intercepts all subsequent requests, decrypts them and responds with their responses
- It looks like you're talking to the server...
- Certificate Authorities (CA) can fix that

Certificate Authority (CA)

- A CA is a trusted source with a known public key
 - Public key is pre-installed in your browser (Called a root CA)
 - Assume no man-in-the-middle attack during your browser download and installation
- The CA issues certificates for domains and subdomains
 - You verify that you control the domain
 - Send them your public key
 - They send you a certificate

Certificate Authority (CA)

- Certificate includes
 - Your public key
 - Domain name and CA name
 - A cryptographic signature of a hash of the certificate body
 - The signature uses the CA's private key so you can verify it with their pre-installed public key that this was in fact issued by the CA
 - Man-in-the-middle cannot fake this without the CA's private key!

Certificate Authority (CA)

- Key chain
 - Not all CA public keys are pre-installed in your browser
 - A CA can have their public key certified by a root CA
 - A domain must provide a key chain that leads to a root CA
- Example key chain
 - Let's Encrypt certificate is signed by DST Root CA
 - Let's Encrypt will sign your certificate
 - Your key chain contains your public key signed by Let's Encrypt and Let's Encrypt's certificate signed by DST
 - Your browser starts with it's installed DST cert to verify the chain
- If a cert cannot be verified by a root CA it is called Self-signed and should not be trusted

Certificates
